# LOCAL VOLUME TABLES FOR CEDRUS DEODARA OF GILGIT-BALTISTAN 

Anwar $\mathrm{Ali}^{1}$, Muhammad Iftikhar ${ }^{2}$, Sajjad Ahmad ${ }^{3}$, Ayaz Khan ${ }^{4}$ and Sultan Muhammad ${ }^{5}$

#### Abstract

The accuracy of growing stock estimates depends on the availability of local volume tables to infer volume of trees from forest inventory data. The current study was undertaken to prepare local volume tables for Cedrus deodara of Gilgit-Baltistan (GB). Data was collected from 52 sample trees which were measured for the study in natural dry temperate forests of Gilgit-Baltistan. Diameter at Breast Height (DBH) and total height of the sample tree were measured before felling. After felling, the bole was cut into 2 m logs with end log of variable length. The over bark mid diameter of the log and its length were measured for determining volume of logs. Total volume of a tree was determined by adding volumes of all logs. Different regression models were tested for deterring best relationship between DBH and height and DBH and Volume. On the basis of the best fit models, volume tables were prepared in 2 cm dbh classes. These tables yielded volume estimates closer to the actual values obtained field measurement.

## INTRODUCTION

The use of volume tables to the management of coniferous forests of North West Pakistan dates back to 1920's when Kulu averages worked out by Sir Gerald Trevor were applied in almost all working plans of these forests. Later on, Standard and Local Volume Tables were prepared for coniferous forests of different areas of Pakistan. However, no volume table was prepared for the natural forests of Gilgit-Baltistan. Volume Tables prepared for other areas were applied for estimation of growing stock in the forests of Gilgit-Baltistan.

Gilgit-Baltistan is situated in the extreme north of Pakistan, bordering China and Afghanistan in the north ( $35^{\circ}-37^{\prime}$ ) and India in the east ( $72^{\circ}-75^{\prime}$ ), covering an area of 72,496 square kilometers. Gilgit-Baltistan hosts valuable forest ecosystems. The total forest area of Gilgit-Baltistan is 337,491 ha. Major forest tree species of GB include Cedrus deodara (Deodar), Pinus wallichiana (Kail), Abies pindrow (Fir), Picea smithiana (Spruce), Pinus gerardiana

[^0](Chilghoza) and Quercus ilex (Oak). Accurate estimates of growing stock in the forests are not possible without local volume tables of the tree species.

Cedrus deodara locally called as deodar or Himalayan cedar is a magnificent coniferous evergreen tree, $45-60 \mathrm{~m}$ tall with a diameter of 0.8 to 1.1 m (Sheikh, 1993). It has high cultural value in the Indian Subcontinent. It is the national tree of Pakistan and is held in high esteem not only for its vigour, beauty and age but also for the fragrance and remarkable qualities of its wood. Deodar wood is the strongest among the Himalayan conifers and comparable to teak in properties.

The volume tables were prepared using different allomteric equations based on regression models. These tables give over bark and under bark estimates of small wood, timber and total volume of given tree species both in metric as well as British units. As the forests of Gilgit-Baltistan are under tremendous pressure due to increasing demand for timber and fuelwood, the use of current volume tables to forest working plans will help in minimizing the overexploitation of the forests.

## MATERIAL AND METHODS

Basic data for preparation of the current volume tables was collected during a study primarily designed for development of 'Local Biomass and Carbon Tables for Major Tree Species of Gilgit-Bbaltistan' during April-September, 2015. As the biomass study involved destructive sampling and felling of sample trees, the sample size was kept low. However, additional trees were measured for preparation of dia-height functions and volume estimation by taking data from standing sample trees by climbing them. Where the trees could not be climbed, the measurements were taken with Spiegel Relaskop. In total 52 trees were measured for volume estimation of deodar out of which 32 were felled for measurement whereas 20 trees were measured in standing position. For determination of dia-height function 59 trees were measured in different deodar stands in the area. DBH of the sample trees ranged from 8 cm to 123 cm whereas height ranged from $4.5-44 \mathrm{~m}$. Sample trees were arranged in diameter classes of 5 cm from 6 to 125 cm . For determination of height functions, additional trees were measured to cover any variation in height due to site quality, slope and aspect. In each diameter class, 2-3 sample trees were randomly selected and measured. Efforts were made to select trees of normal form and shape to closely represent the forest stands of the area. Trees with broken top, forked stem, excessive or less branching or any other abnormality were avoided. The detail of sample trees measured is given in table 1.

Table 1. Detail of sample trees used in the preparation of volume table

| Function | Range of dbh <br> $(\mathrm{cm})$ | Range of heights <br> $(\mathrm{m})$ | Number of sample <br> trees |
| :--- | :---: | :---: | :---: |
| Tree Height | $8-152$ | $4.5-44$ | 59 |
| Total Volume | $8-123$ | $4.5-42$ | 52 |

Diameter at Breast Height (DBH) and total height of the sample tree were measured before felling. After felling, the bole was cut into 2 m logs with end log of variable length. The over bark mid diameter of the log and its length were measured for determining volume of logs using Huber's formula. Big branches upto 20 cm diameter at thin end were included in timber measurement whereas small branches upto 5 cm diameter at thin end were included in small wood. Volume upto 5 cm overbark diameter at the thin end of the stem including branches was taken as total volume of the tree, whereas volume upto 20 cm diameter over bark at the thin end of the stem including branches was taken as timber volume of the tree. The volume from 20 cm down to 5 cm over bark of the stem and branches was accounted as volume of small wood of the tree. Total volume of a tree was determined by adding volumes of all logs upto 5 cm at the thin end.

The method employed for development of the current volume tables consists of two stages. In the first stage an analytical relationship was developed between DBH and height and in the second stage allometric equations were developed for estimation of timber and total volume using various regression models. The following regression models were used for estimating height, timber volume and total volume for each species.
i. Models for Height Estimation
$\mathrm{H}=\mathrm{a}+\mathrm{bD}$.
$H=a+b D+c D^{2}$
$H=a+b \ln (D)$
ii. Models for Timber Volume Estimation
$T M=a+b D+c D^{2}$
$T M=a+b\left(D^{2} H\right)+c\left(D^{2} H\right)^{2}$
$T M=\mathrm{aD}^{\mathrm{b}}$.
$T M=a\left(D^{2} H\right)^{b}$.
iii. Models for Total Volume Estimation
$T V=a+b D+c D^{2}$.
$T V=a+b\left(D^{2} H\right)+c\left(D^{2} H\right)^{2}$
$T V=a D^{b}$
$T V=a\left(D^{2} H\right)^{b}$

Where
$\mathrm{D}=$ Diameter over bark at Breast Height in cm
$\mathrm{H}=$ Total height of tree in m
TM $=$ Timber Volume in $\mathrm{m}^{3}$
TV $=$ Total Volume in $\mathrm{m}^{3}$
In = Natural Logarithm
a = regression constant
b, c = regression coefficients
All the above mentioned models were tested for the species and the model which showed best performance on the following criteria was finally selected.
i. Minimum sum of square of the residual error
ii. Minimum standard error of the estimate
iii. Maximum value of $R^{2}$

## RESULTS AND DISCUSSIONS

## Height Estimation

Out of the three models for height estimation, Model No. 3 gave best performance on the given criteria and also yielded reasonable height estimates for large size trees in which height growth is almost stopped (Figure 1). Based on this model, the following regression equation was developed.

$$
H=-34.394+15.355 \ln (D)
$$

The equations alongwith indices of best fit for the selected models are given in the Table No. 2 .

Table 2. Regression Models alongwith indices of best fit

| Estimate | Regression <br> Model | Allometric equation | $N$ | SEE <br> $(\%)$ | SS of <br> Residuals | $R^{2}$ |
| :--- | :--- | :--- | :---: | :---: | :---: | :---: |
| Height | $\mathrm{H}=\mathrm{a}+\operatorname{lnD}$ | $\mathrm{H}=15.355 \ln (\mathrm{D})-34.394$ | 59 | 5.52 | 1733.47 | 0.743 |
| Timber Volume | $\mathrm{TV}=\mathrm{a}+\mathrm{b}\left(\mathrm{D}^{2} \mathrm{H}\right)+$ <br> $\mathrm{c}\left(\mathrm{D}^{2} \mathrm{H}\right)^{2}$ | $\mathrm{TV}=4 \mathrm{E}-12\left(\mathrm{D}^{2} \mathrm{H}\right)^{2}+$ <br> $2 \mathrm{E}-05\left(\mathrm{D}^{2} \mathrm{H}\right)+0.0478$ | 49 | 16.31 | 22.19 | 0.984 |
| Total Volume | $\mathrm{V}=\mathrm{a}\left(\mathrm{D}^{2 H}\right)^{\mathrm{b}}$ | $\mathrm{TV}=4 \mathrm{E}-05\left(\mathrm{D}^{2 H}\right)^{0.9733}$ | 52 | 16.37 | 16.14 | 0.989 |

Fig. 1 Dia-Height Function for deodar

## Timber Volume Estimation

Model No. 5 showed best performance on the given criteria and also yielded timber estimates nearer to actual values of timber volume for given sample trees. The indices of best fit are given in table 2. The graphical representations of the model is shown in figures. Based on this model, the following regression equation was developed for estimation under bark timber volume.

$$
T V=+0.0478+2 \mathrm{E}-05\left(\mathrm{D}^{2} \mathrm{H}\right) 4 \mathrm{E}-12\left(\mathrm{D}^{2} \mathrm{H}\right)^{2}
$$

Fig.2. Deodar Timber Volume Model

## Total Volume Estimation

Out of four models tested for estimation of total volume, Model No. 11 showed best performance on the given criteria and yielded total volume estimates closer to actual values. The indices of best fit are given in table 2. The graphical representations of the model is shown in figures. Based on this model, the following regression equation was developed for estimation of total volume.

$$
\mathrm{TV}=4 \mathrm{E}-05\left(\mathrm{D}^{2} \mathrm{H}\right)^{0.9733}
$$

Fig 3. Deodar Total Volume Model
The total volume yielded by the above regression model was also compared with the estimates produced by the existing volume table for Upper Indus Kohistan which is adjacent to the study area and has similar climatic conditions. The result is given in table No.3. It is evident from the data that the current volume tables gave estimates of total volume closer to the actual values obtained from field measurement. The current volume table over estimated by $2.3 \%$ compared to $20.1 \%$ underestimation by the volume table of Indus Kohistan. Thus it is advisable to use the current volume tables for estimating growing stock in the study area.

Table 3. comparison of total volume with actual and existing volume table

## Use of Volume Tables

Volume Tables were prepared on the basis of selected regression models both in metric as well as British units. The Volume Tables given in the appendix I and II were prepared by 2 cm diameter class interval in metric units and the tables from 6 to 10 were prepared by 1 inch diameter class intervals in British units. Diameter classes show mid values for the range of diameters. For example 50 cm DBH class include trees with DBH 49.1 to 51.0 cm in metric units. On the other hand, 20 DBH class includes trees ranging from 19.6 to 20.5 inches in British units. These tables provide under bark estimates of timber and total volume. The small wood volume estimates can be obtained by subtracting timber from the total volume of the tree. In order to obtain over bark estimates, multiply the volume table figures by 1.18.

## CONCLUSION

Cedrus deodara growing in dry temperate forests of Gilgit-Baltistan show different growth pattern from the species found in other forest areas of Pakistan. It is, therefore, necessary to prepare local volume tables for the species. Results showed good relationship between volume as dependent variable and DBH and height as independent variables. The $R^{2}$ was found to be 0.98 and Relative Standard Error of Estimate was found as $16.37 \%$ which indicated good fit of the model. The total volume yielded by the given regression equation was also compared with the estimates produced by the existing volume table for Upper Indus Kohistan which is adjacent to the study area and has similar climatic conditions. It was found that the current volume tables gave estimates of total volume closer to the actual values obtained from field measurement. The current volume table over estimated by $2.3 \%$ compared to $20.1 \%$ underestimation by the volume table of Indus Kohistan. Thus it is advisable to use the current volume tables for estimating growing stock in the study area.
